

Weight Watcher2 Demo

Stateless CEP Decision Service Use Case
For the Vagrant CDK
and JBoss Drools 6.3.0.FINAL
as tested on OS/X El Capitan

1 Introduction

1.1 Overview

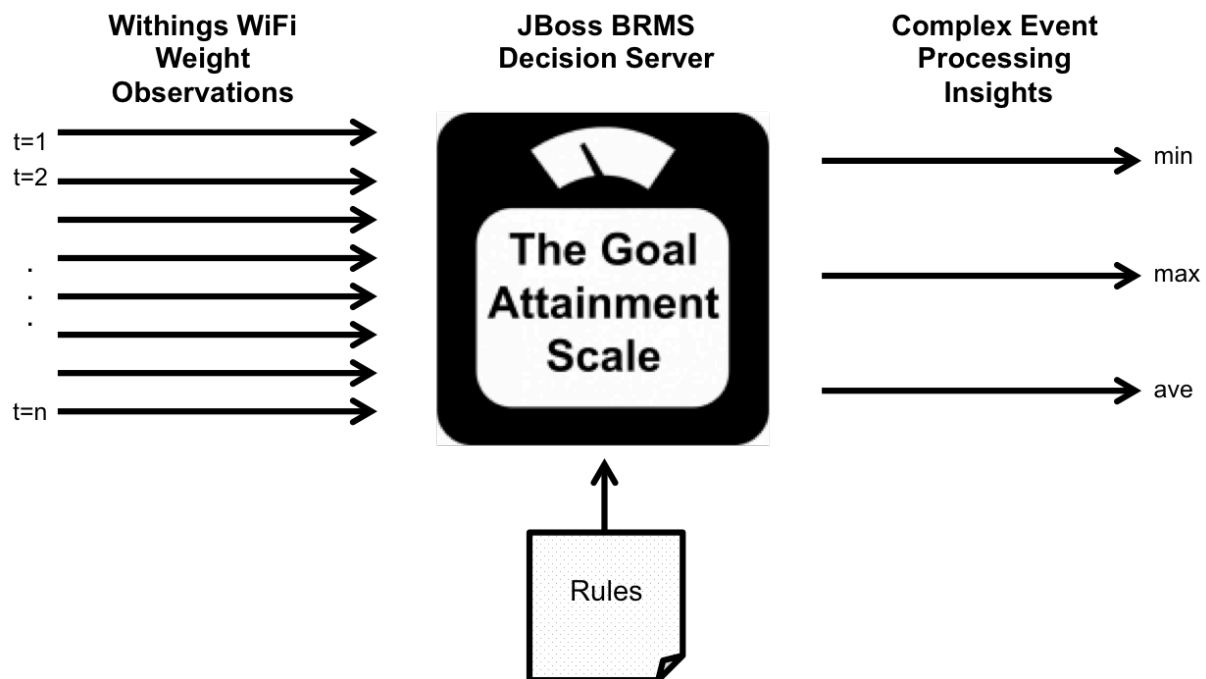

Interested in a demo that gets you started with OpenShift and showcases the Drools (6.3.0.FINAL) Decision Service?* Then look here. The application is a stateless Decision Service with complex event processing (CEP) support based on a pseudo clock.

An example use case demonstrated includes a (REST) client sending a time series of *facts* in the form of weight observations to the Decision Service. The Decision Service then reasons over the inputs to derive CEP insights such as average weight, least weight and weight change of a rolling time window. These insights are returned to the calling client as *facts*.

This is a facts-in-facts-out (FIFO) pattern using a standardized fact interface representation. This technique makes it easier for a simple thin client application such as php, cURL, SoapUI or RStudio to send request/response payloads to the Decision Service without knowledge of the underlying rules data model.

<http://blog.emergile.com/2014/12/08/really-simple-rules-service/>

Note that by porting to the Drools 6.3.0.FINAL release, this demonstration application is ready for OpenShift Enterprise V3.1 and xPaaS support such as with JBoss BRMS 6.2. Docker image based deployments are supported in both OpenShift V3 mode and basic Docker.

* The Decision Service also goes by the name of KIE Server, Decision Server and Realtime Decision Server

1.2 Learning Goals

We are going to showcase some use cases using the all-in-one Vagrant virtual machine (VM) for OpenShift Origin located at <http://www.openshift.org/vm/> . If you have access to a working OpenShift installation you can omit any setup instructions specific to Vagrant and proceed directly to application setup and use cases.

Note that the OpenShift PaaS provides first class native support for Docker image based container specification and leverages Kubernetes for container (pod) life-cycle management. The learning outcomes of this Demonstration include:

- Install your own OpenShift 3 Vagrant VM CDK
- Install a local DNS service using dnsmasq
- Configure OpenShift 3 to use the local DNS service
- Learn how to pull down Docker images and build new OpenShift applications
- Access the OpenShift locally using URL routes such as *.cloudapps.example.com
- Familiarise yourself with the OpenShift 3 Developer console
- Familiarise yourself with the Drools Work console
- Test out various Drools Decision Service REST APIs using clients such as pHp, RStudio, cURL and SoapUI
- Learn how to change rules using the Workbench and oc rsync the changes to the Decision Service
- A little taste of xPaaS!

1.3 Prerequisites

- Minimum of 4 Mbytes of free available RAM
- Quad core processor
- At least 10 GBytes of free available disk space
- Vagrant
- Docker Toolbox
- VirtualBox
- MySQL Workbench
- SoapUI
- CDK all-in-one Vagrant image for OSE

2 Setup OpenShift 3

Create a working directory <DEMO-HOME> for your demonstration such as ~/Vagrant/OpenShift and clone down the main repository for the demo located at:

```
$ cd <DEMO-HOME>
$ git clone https://github.com/StefanoPicozzi/weightwatcher2
```

2.1 Vagrant VM CDK

Follow these instructions that follow to download, install and prepare the your host with dnsmasq and the guest Vagrant VM. The steps are documented assuming OS/X (El Capitan) and can be summarised as per below.

1. Install the all-in-one OSE CDK VM as available at:
https://access.redhat.com/downloads/content/293/ver=2/rhel---7/2.0.0/x86_64/product-software
2. Setup a dnsmasq service on your host machine
3. Configure your OpenShift Origin VM to reference your dnsmasq service

The setup instructions are currently predominantly manual and OS/X centric - but can be automated and generalised with tools such as Ansible and simplified with the incorporation of a separate VM to host the DNS service. That's on the to-do-list for the Community. The demonstration functions in disconnected (offline) mode subject to notes in Enhancements section.

2.2 dnsmasq Install

```
// Launch a docker terminal window such as with Docker Toolbox
// Find the <DNS-IP> of your docker shell, e.g. 192.168.99.100
$ docker-machine ls
$ cd <DEMO-HOME>

$ docker pull spicozzi/dnsmasq
// Edit address entry to reflect your Vagrant VM
$ vi dnsmasq.conf
    address=/.example.com/10.1.2.2

$ cd weightwatcher2/src/dnsmasq
./docker-run.sh
```

```
// Set Host to use <DNS-IP> as DNS server

// Desktop Menu > System Preference > Network
// Select your network connection
> Advanced ... > DNS

// Add <DNS-IP> to top of DNS Servers:
// Add cloudapps.example.com to top of Search Domains:

// Check ANSWER SECTION: for 10.1.2.2
$ dig testdrive.cloudapps.example.com
```

2.3 OpenShift Enterprise CDK Vagrant Install

```
$ cd <DEMO-HOME>
$ vagrant box list
$ vagrant halt
$ vagrant destroy
$ vagrant box remove --force cdkv2

// Install the Vagrant OSE CDK VM
// Visit https://access.redhat.com/documentation/en/red-hat-enterprise-linux-atomic-host/version-7/container-development-kit-installation-guide/#installing\_the\_cdk\_on\_mac\_os\_x
// Follow the documented installation instructions
$ vagrant box add --name cdkv2 rhel-cdk*.box
$ vagrant box list

// Install the OpenShift Enterprise CLI tools
// Visit https://access.redhat.com/downloads/content/290/ver=3.1/rhel---7/3.1.1.6/x86\_64/product-software
// Follow the documented installation instructions
$ oc version

// Make a few changes to the shipped CDK Vagrantfile
$ vi Vagrantfile
  config.registration.username = '*****'
  config.registration.password = '*****'
  v.memory = "4096"
```

2.4 Vagrant VM Final Preparation Steps

```
$ cd <DEMO-HOME>
$ vagrant up
$ vagrant ssh
$ sudo su -
# yum install -y bash-completion
# yum install -y /usr/bin/dig
# yum install -y /usr/bin/locate
# updatedb
# git clone https://github.com/StefanoPicozzi/weightwatcher2

// Edit /etc/resolv.conf and prevent NetworkManager overwrite
// The first nameserver points to your Host <IP> address
# chattr -i /etc/resolv.conf
# vi /etc/resolv.conf
    search cluster.local .cluster.local
    nameserver 192.168.99.100
    nameserver 10.0.2.3
# chattr +i /etc/resolv.conf

// Verify ANSWER SECTION: reports 10.1.2.2
# dig testdrive.cloudapps.example.com

// To become a cluster admin and inspect nodes
$ vagrant ssh
$ oc login --username=system:admin -n default --certificate-
authority=/var/lib/origin/openshift.local.config/master/ca.crt
$ oc get nodes
```

3 Setup Demonstration Applications

Once you have completed these prerequisite OpenShift Origin guest VM and host dnsmasq steps you can move onto setting up the demonstration OpenShift application and use cases. We are going to create three OpenShift (Docker-image-based) applications for the weightwatcher Decision Service, the companion website and another to host RStudio Server. The setup steps are summarised as follows:

1. Verify your environment. Do this every time before you try the demo.
2. Make some configuration changes (as root) to your OpenShift Origin system.
3. Create the applications as a Developer user (as admin)

3.1 Environment Checklist

```
$ cd <DEMO-HOME>

// Check dnsmasq OK
$ cd weightwatcher2/src/dnsmasq
// Check address setting points to the Vagrant VM location
$ cat dnsmasq.conf
// Check external nameserver setting is correct
$ cat resolv.dnsmasq.conf
./docker-run.sh

// Check Vagrant VM OK
$ vagrant status
$ vagrant up
$ vagrant ssh
$ sudo su -
// Check nameserver entry points to your dnsmasq
# cat /etc/resolv.conf

// Check local DNS ANSWER SECTION: for 10.1.2.2
$ dig testdrive.cloudapps.example.com
// Check external DNS configured correctly
$ ping www.google.com
```

3.2 Demo Setup as OpenShift root User

```
$ cd <DEMO-HOME>
$ vagrant status
$ vagrant up
$ vagrant ssh
$ sudo su -

# mkdir -p /home/data/mysql
# chmod -R 777 /home/data/mysql
// Check OpenShift security context constraints is RunAsAny
# oc edit scc restricted
    allowHostDirVolumePlugin: true
    runAsUser
        type: RunAsAny

// Pull down the images
# docker pull openshift/php-55-centos7
# docker pull openshift/mysql-55-centos7
# docker pull spicozzi/weightwatcher2
# docker pull spicozzi/workbench
# docker images
```

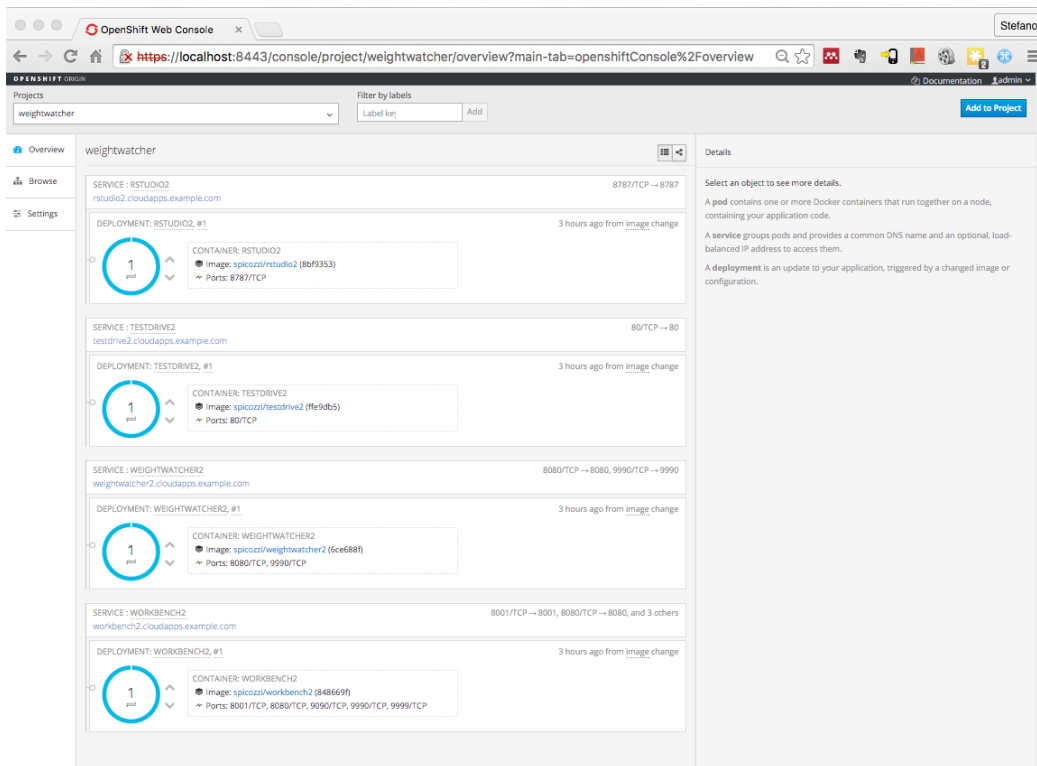

```
$ cd <DEMO-HOME>
$ oc login 10.1.2.2:8443 --insecure-skip-tls-verify=true
Username: test-user
Password: test-user

$ oc delete project weightwatcher
$ oc new-project weightwatcher
```

4 Standard Use Cases

4.1 OpenShift Developer Console Tour

Open your browser at the address of the OpenShift Developer application – <https://10.1.2.2:8443>. Login as admin/password and tour around the application and try out some of the features such as inspecting the log files of a running pod and logging into a container.

4.2 Docker Image to Create Decision Service

Here we will create the Decision Service based on an existing Docker image. These samples assumes you have cloned down <https://github.com/StefanoPicozzi/weightwatcher2> . Some simple cURL scripts have also been supplied to test the health of your configuration are located under the /tools/cURL. These are similar to the test cases available at the companion website and assume weightwatcher.cloudapps.example.com as the Decision Service endpoint. Edit each script to change the `http://FQDN:PORT` if necessary:

```
$ cd <DEMO-HOME>
$ oc login 10.1.2.2:8443 --insecure-skip-tls-verify=true
Username: test-user
Password: test-user

$ oc project weightwatcher
$ oc delete all -l name=weightwatcher
$ oc new-app spicozzi/weightwatcher2 --name=weightwatcher -l
name=weightwatcher

// Assign a route
$ oc get svc
$ oc expose service weightwatcher --name=weightwatcher -l
name=weightwatcher --hostname=weightwatcher.cloudapps.example.com

$ oc status
$ oc get all -l name=weightwatcher
$ oc get dc -o json

$ cd tools/cURL
// Smoke test the new app

$ oc scale --replicas=5 dc weightwatcher
$ ./post-facts.sh
$ oc scale --replicas=3 dc weightwatcher
$ ./post-facts.sh
$ oc scale --replicas=1 dc weightwatcher
$ ./post-facts.sh
```

4.3 Source To Image to Create Companion Website

Here we will create a companion website using the source to image feature.

```
$ cd <DEMO-HOME>

// Create and note the location of a fork of the Git repo at
https://github.com/StefanoPicozzi/testdrive

$ oc delete all -l name=testdrive

// Create the app using the CLI or Console using your forked GitHub
$ oc new-app openshift/php-55-
centos7~https://github.com/StefanoPicozzi/testdrive --name=testdrive -l
name=testdrive strategy=source -e MYSQL_USER=sa MYSQL_PASSWORD=password
MYSQL_DATABASE=nudgedb MYSQL_SERVICE_HOST=172.30.19.57

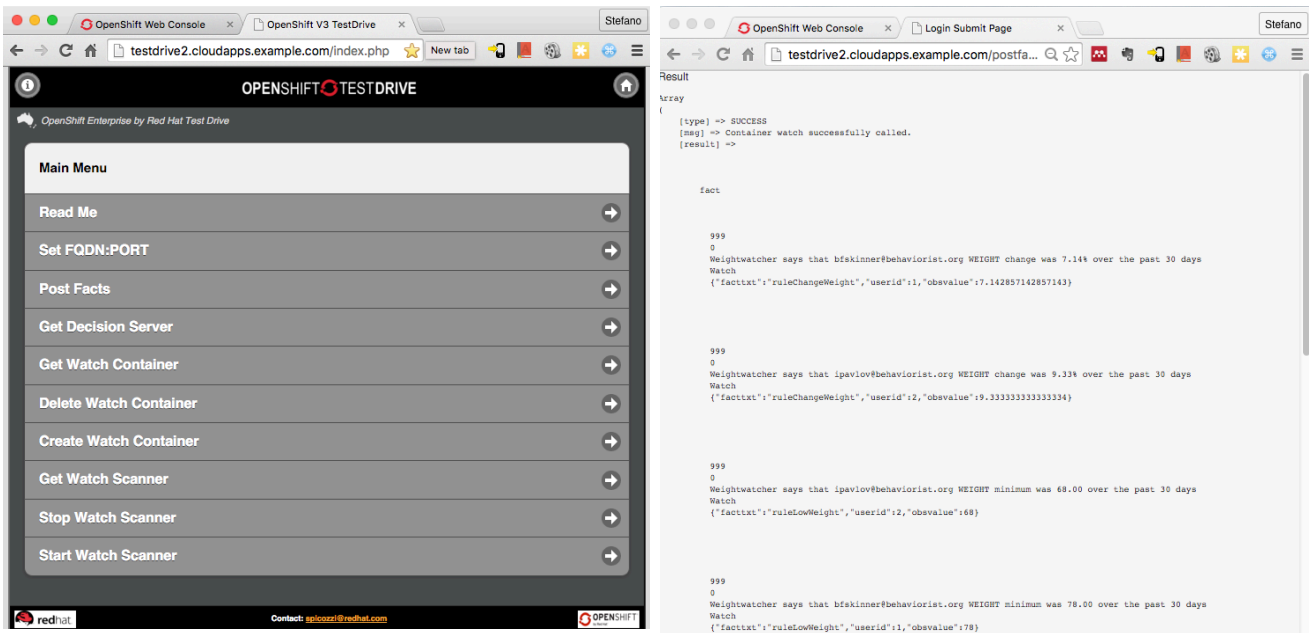

# Get the build <NAME>
$ oc get builds
$ oc build-logs <NAME> -f

// Assign a route
$ oc expose service testdrive --name=testdrive -l name=testdrive --
hostname=testdrive.cloudapps.example.com

// Explore the new app
$ oc status
$ oc get all -l name=testdrive
$ oc describe bc testdrive
$ oc edit bc testdrive -o json
```

Open your browser at the address of the PHP companion application – testdrive.cloudapps.example.com. This showcases some of the many Decision Service REST APIs.

Set the FQDN:PORT to point to your Decision Service instance which defaults to weightwatcher.cloudapps.example.com and click Submit to save. Now try the Post Facts menu option to verify that it is accepting requests correctly. Output should look similar to the below in the side-by-side screen shots. The other choices refer to other optional Decision Service API features and test cases that are documented separately.

4.4 Drools Workbench Tour

The demonstration stands up the Drools Workbench so you can use the Console to edit and create rule. First we need to build our Workbench application on OpenShift.

```
$ vagrant ssh
$ sudo su -

# cd weightwatcher2/src/workbench
// Repo space limitations mean the drools-wb and kie-server
// war files need to be manually located and copied
// across to the deployments directory.
# docker build -t spicozzi/workbench .

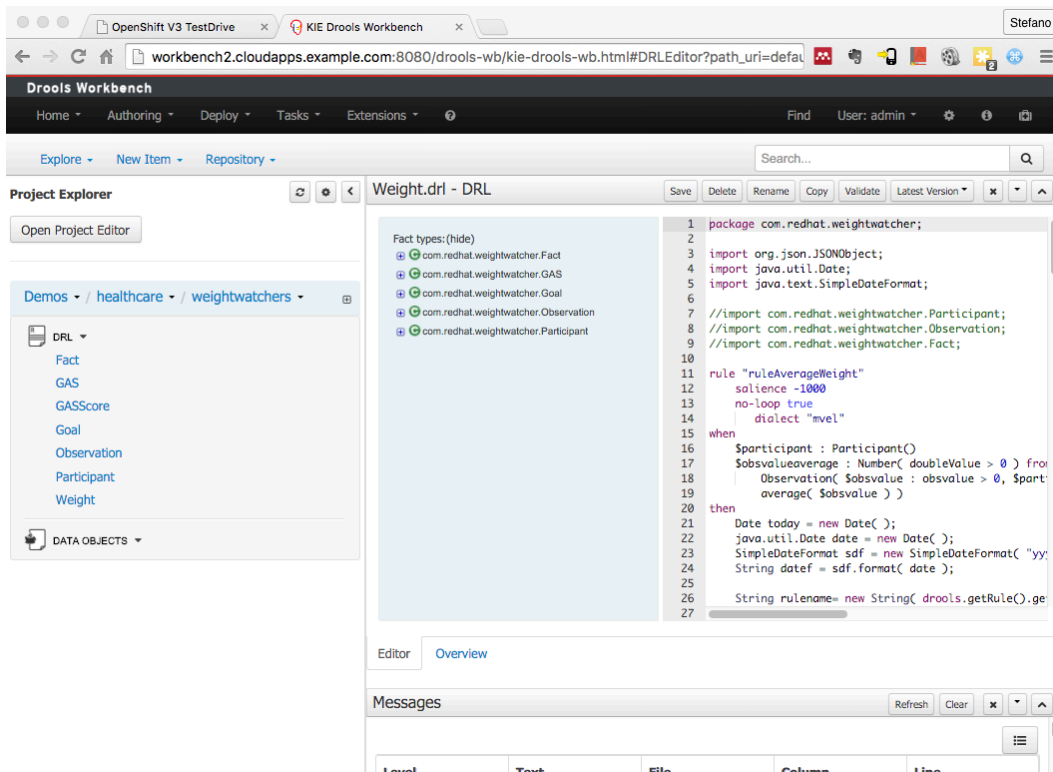

// Alternatively just pull down the ready made image
# docker pull spicozzi/workbench
```

```
$ cd <DEMO-HOME>
$ cd weightwatcher2/src/workbench
$ oc delete all -l name=workbench
$ oc delete -f workbench.yaml
$ oc create -f workbench.yaml
$ oc deploy workbench --latest -n weightwatcher

// Assign a route
$ oc get svc
$ oc expose service workbench --name=workbench -l name=workbench --
hostname=workbench.cloudapps.example.com

$ oc status
$ oc get all -l name=workbench
$ oc get builds
```

Now open your browser at the address of the Drools Workbench – workbench.cloudapps.example.com/drools-wb - and login as admin/admin. Tour around the application and try out some of the features such as inspecting the supplied project, DRL files and Data Models. You may use this later if you wish to change some of the rules and apply the changes to the Decision Service.

4.5 SoapUI Samples

These samples assume you have SoapUI installed on your workstation and that you have cloned down <https://github.com/StefanoPicozzi/weightwatcher2>. Launch SoapUI and then import the project with a name that includes the label "Business APIs" as located at `weightwatcher2/tools/SoapUI`. Add a HEADER to the SoapUI POST invocations as follows:

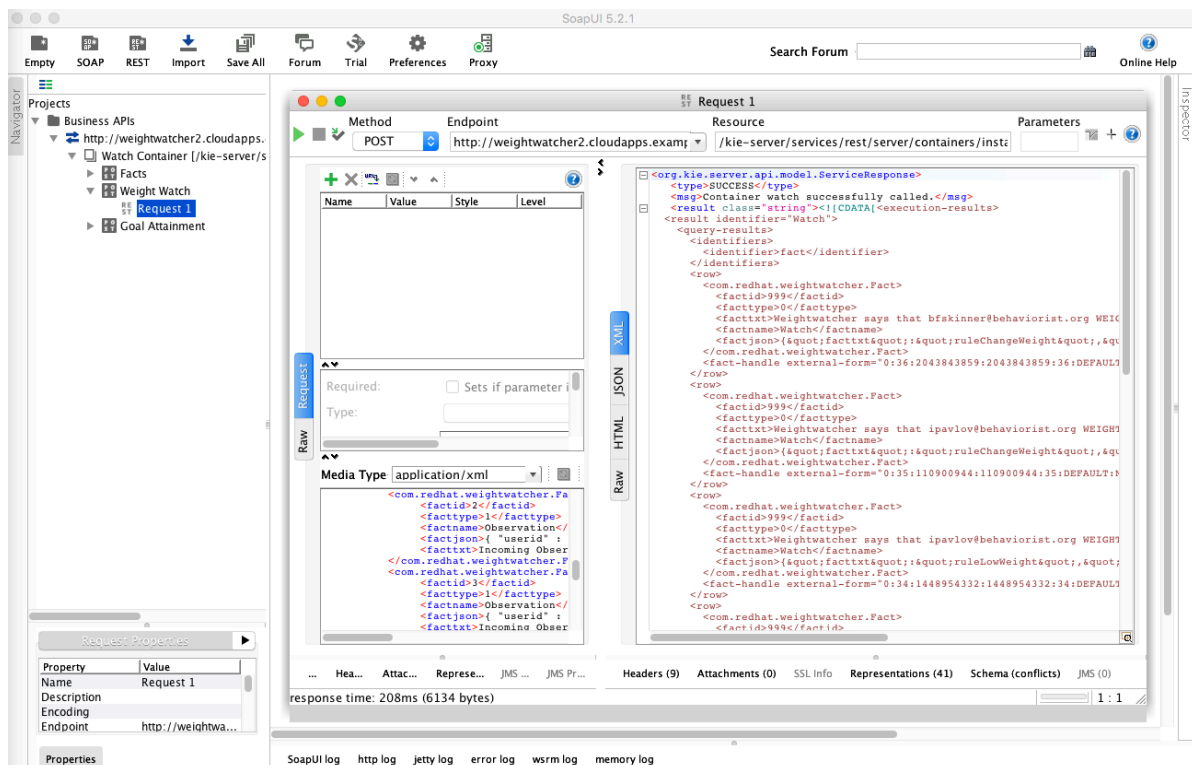

X-KIE-ContentType: XSTREAM

The 3 supplied resources and REST POST requests are samples representing the following.

"Facts" shows a simple request in which a request payload of facts are *inserted* into the Decision Service knowledge base and then a *query* is issued to verify this action has been successful.

The "Weight Watch" sample shows an invocation in which a set of facts containing weight measurements is sent to the Decision Service. CEP rules are then applied to derive insights as per the response payload. The request consists of facts representing Participant, Goal and Observation data records. The Participant records capture details of the user, Goal captures the Participant's target weight objectives and Observation records a time series of weight measurements. The response payload then returns a set of facts reporting minimum, maximum and weight change statistics over a sliding time window.

The "Goal Attainment" sample demonstrates a use case in which the Participant has elected to enter into a period of intermittent fasting, known as the Fast Diet <http://thefastdiet.co.uk/>. The GAS fact represents the Participant's number of fasting day goals over the week, described in ranges of worst through to best outcomes, refer http://en.wikipedia.org/wiki/Goal_Attainment_Scaling for details on the method. The Observation records then report back actual days of fasting in the previous weeks. The Decision Service then responds back with performance against goals. The GAS fact table is a candidate for remodelling using, e.g. a Guided Decision Tables.

4.6 R using RStudio

The demonstration shows R script using RStudio Server as a client interacting with the Decision Service. First we need to build our RStudio Server application on OpenShift.

```
$ vagrant ssh
$ sudo su -

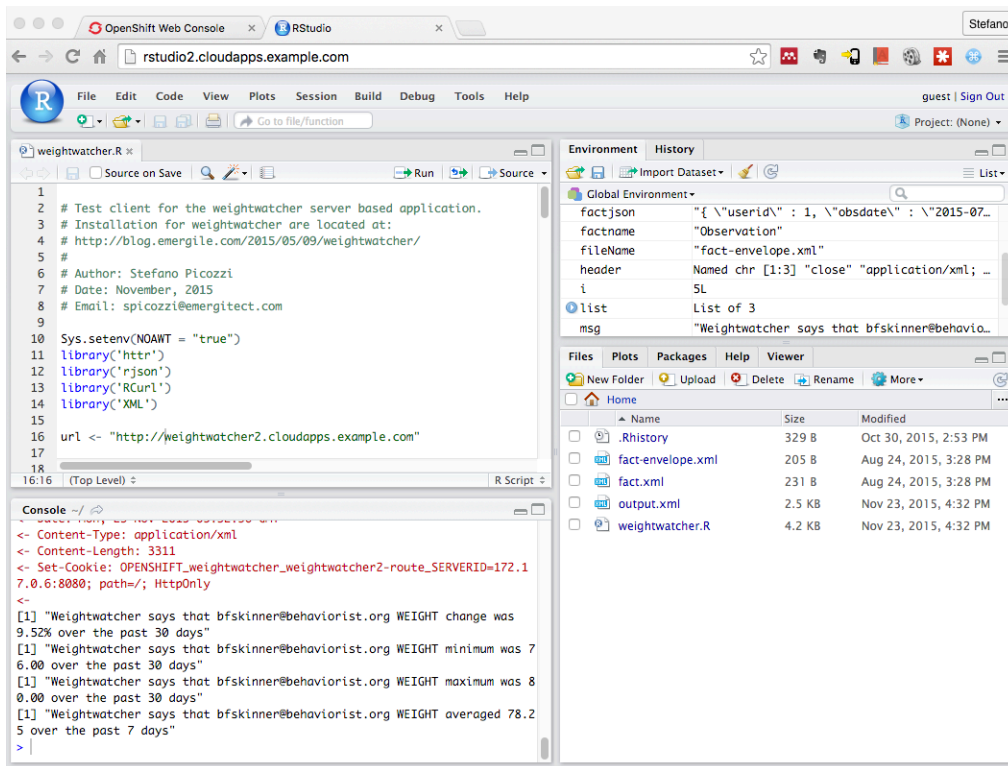

# oc get images -n openshift | grep rstudio
# oc delete image -n openshift <NAME>
# cd weightwatcher2/src/rstudio
# docker build -t spicozzi/rstudio .
```

```
$ cd <DEMO-HOME>
$ cd weightwatcher2/src/rstudio
$ oc delete all -l name=rstudio
$ oc create -f rstudio.json
$ oc deploy rstudio --latest -n weightwatcher

$ oc expose service rstudio --name=rstudio -l name=rstudio --
hostname=rstudio.cloudapps.example.com

$ oc status
$ oc get all -l name=rstudio
```

Launch the RStudio pod – `rstudio.cloudapps.example.com`. Login as `guest/guest`. Edit the `weightwatcher.R` script URL end point to reflect your environment if necessary, then source to run. Inspect the R script for hints of techniques on how to prepare, send and receive payloads between R and the Decision Service.

```
// Now that you've finished with rstudio why not scale it down to zero
$ oc scale --replicas=0 dc rstudio

// To restore the rstudio pod scale it up to one
$ oc scale --replicas=1 dc rstudio
```

5 Advanced Use Cases

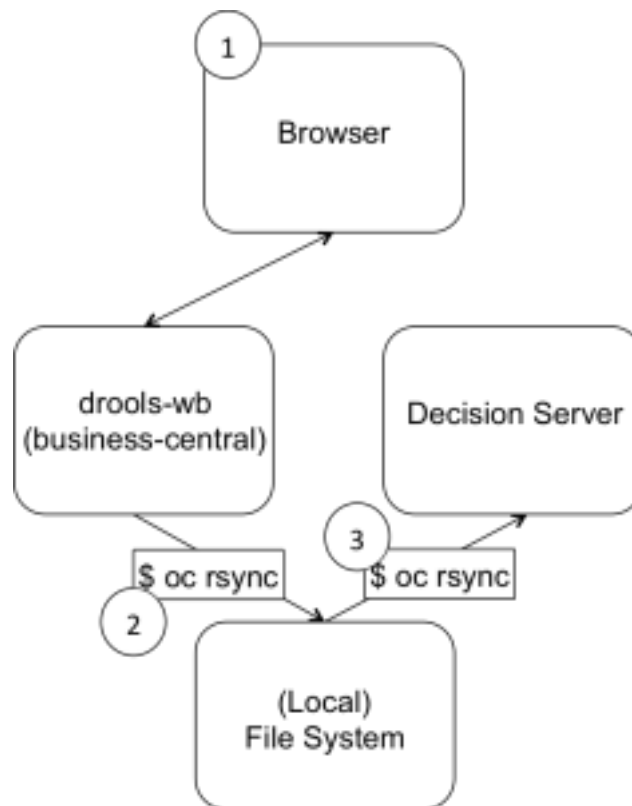

5.1 External Database access

Refer to `weightwatch2/src/mysql` for sample code and snippets relevant to this example.

- Create and launch a docker MySQL database container on your host machine
 - `MSQL_USER=sa`
 - `MYSQL_PASSWORD=password`
 - `MYSQL_DATABASE=nudgedb`
 - Create a table named "user" with a column attribute "username"
 - Populate with some sample values
- Configure the OpenShift mysql service and endpoints for your project
- Test by selecting the "Test Mysql access" option in the testdrive app
 - Note than an easy way to change the MYSQL environment variables is by logging into the pod and either
 1. editing the `getdbusers.php` file directly
 2. resetting the environment variables as needed

5.2 Rule Changes using oc rsync

A more advanced rule change use case is also documented later that makes use of the OpenShift (oc) rsync feature. Basic schematic as follows. Refer also <http://blog.emergile.com/2015/11/16/drools-rules-rsynchronicity/>

5.2.1 Start the Decision Service Scanner

```
// This is necessary so that the Decision Service will pick up rule changes
// Launch a Browser and point it to testdrive.cloudapps.example.com
// Click the Start Watch Scanner menu option
// Click the Get Watch Scanner menu option to verify
```

5.2.2 Rule Changes using Workbench

```
// Launch a Browser to workbench.cloudapps.example.com/drools-wb
// Login as admin/admin

// Use the workbench GUI to make some changes to a DRL file
// Click build & deploy to save the changes to the rules .jar file

$ cd ~/Vagrant/OpenShift
// Now oc rsync the repository directory to your local file system

// First find the NAME of the pod
$ oc get pods | grep workbench

// Now pull down the rules repo
$ oc rsync <NAME>:/opt/jboss/.m2/repository .
```

5.2.3 Apply Rule Changes to the Decision Service

```
// Now rsynch the local repository directory up to the weightwatcher2 pod

$ cd <DEMO-HOME>
// First find the NAME of the pod
$ oc get pods | grep weightwatcher2

// Now push up the rules repo
$ oc rsync repository <NAME>:/opt/jboss/.m2

// Check that the scanner has picked up the changed rules file
$ oc logs -f <NAME>

// Launch a Browser and point it to testdrive.cloudapps.example.com
// Click the Post Facts menu option to verify changes applied
$ oc logs -f <NAME>
```

6 Extras

6.1 Metrics

```
$ vagrant ssh
$ sudo su -

# oc project openshift-infra

// Now follow documentation as at:
//
https://docs.openshift.com/enterprise/latest/install\_config/cluster\_metrics.html

# systemctl restart openshift
```

6.2 Image Download

The runtime artefacts for this demonstration application have all been packaged up according to the Docker container specification. The various Docker images can be downloaded directly as follows:

```
# The Decision Service as a Docker image
$ docker pull spicozzi/weightwatcher2

# A companion PHP website with test cases
$ docker pull spicozzi/testdrive

# An optional RStudio Server image with R test case included
$ docker pull spicozzi/rstudio

# An optional JBoss Drools workbench image used for rule changing use case
$ docker pull spicozzi/workbench
```

6.3 Launch Container Instances using Docker Toolbox

You can run launch these images directly from Docker as follows.

```
# Launch 4 terminal windows and run the container instances in each

# Find the IP_ADDRESS used by your instances, e.g.
$ docker-machine ls

# Terminal 1
$ docker run -it -p 81:80 spicozzi/testdrive

# Terminal 2
$ docker run -it -p 8080:8080 spicozzi/weightwatcher2

# Terminal 3 (optional)
$ docker run -it -p 8787:8787 spicozzi/rstudio

# Terminal 4 (optional)
$ docker run -it -p 8081:8080 spicozzi/workbench
```

6.4 Useful (Docker Toolbox) Docker Commands

```
# Find <IP> of Docker virtual machine
$ docker-machine ls

# List of docker images
$ docker images

# List of running docker containers showing <CONTAINER_ID>
$ docker ps -l

$ docker attach <CONTAINER_ID>

# Kill a running docker container with <CONTAINER_ID>
$ docker rm -f <CONTAINER_ID>

# Pull down a docker image
$ docker pull spicozzi/nginx

# Disconnected access to load Docker images
$ docker save -o workbench2.tar spicozzi/workbench2
$ docker load -i workbench2.tar

# Commit changes in a running Container as an image
# From another terminal get the <CONTAINER_ID>
$ docker ps -l
$ docker commit <CONTAINER_ID> spicozzi/nginx

# Assume you have a running container named weightwatcher1
$ docker logs -f weightwatcher1
$ docker rm -f weightwatcher1

# Remove all running containers
$ docker rm -f $(docker ps -aq)

# Remove all untagged images
$ docker rmi -f $(docker images | grep "<none>" | awk '{print $3}')
```

6.5 Useful OpenShift Commands

```
// Explanation of OpenShift concepts
$ oc types
// To scale up replicas
$ oc scale dc weightwatcher2 --replicas=2

// Tail the log file for the created pod
$ oc get pods
$ oc logs -f <PODNAME>

// If you make any errors just delete the <PROJECT> and repeat
$ oc delete project <PROJECT>

// Find the openshift configuration <CONFIG>
# locate master-config
# openshift ex validate master-config <CONFIG>

// Stop/start openshift
# systemctl stop openshift
# systemctl start openshift
# systemctl status openshift

# journalctl -f
# journalctl -f -u openshift-master
# journalctl -f -u openshift-node

# oc get pods | awk '{print $1}'
# oc logs -f `oc get pods | grep deploy | awk '{print $1}'`

# openshift ex diagnostics
oadm policy add-cluster-role-to-user cluster-admin <user name>
oc delete all --all -n openshift-infra
find . -type s -name master-config.yaml -print
```

6.6 Useful Vagrant Commands

```
$ vagrant box remove -f openshift3

# Create image off existing box
$ mkdir <DEMO-HOME>
$ cd <DEMO-HOME>

$ vagrant package --output ../weightwatcher/weightwatcher.box
$ cp Vagrantfile ../weightwatcher

$ cd ~/Vagrant/weightwatcher
$ vi Vagrantfile
:1,$ s/openshift3/weightwatcher/g

$ vagrant box add weightwatcher weightwatcher.box

$ vagrant ssh
$ oc login --username=system:admin -n default --certificate-
authority=/var/lib/origin/openshift.local.config/master/ca.crt
$ oc get nodes
```

6.7 Changing Rules Docker Toolbox example

This demonstration shows a use case in which rule are changed using the JBoss Business Central studio and then those changes reflected in the Decision Service directly from Docker as tested using Docker Toolbox on OS/X. The basic steps are as follows:

1. (Re)launch the JBoss Drools Workbench container (workbench2) with the Maven repository mounted as an external volume (workbench2/m2)
2. (Re)launch the Decision Service container (weightwatcher2) with the Maven repository mounted as an external volume (weightwatcher2/m2)
3. (Re)launch the companion website PHP application (testdrive2)
4. From testdrive2 Browser, click Start Scanner to start the Decision Service scanner
5. From workbench2 Workbench Browser, make some changes to your rules, save them and then build-and-deploy the artefact. Login to Workbench using IP_ADDRESS:8018/drools-wb and credentials admin/admin
6. From the workbench/m2 file system, copy all the contents in com/redhat/demos/weightwatchers/1.0 to your clipboard
7. From the weightwatcher2/m2 file system, paste the clipboard contents to com/redhat/demos/weightwatchers/1.0
8. From testdrive2 Browser, click Post Facts and verify that the changes have been applied
9. From workbench2 container window, check the log for evidence of a change to the rule jar file
10. From weightwatcher2 container window, check the log for evidence of a scanner event to for a new rule jar file

For steps 1 and 2, check the sample Docker launch scripts supplied at the GitHub repository for examples on how to approach the volume attachment requirement. These instructions assume familiarity with authoring rules using Drools Workbench. Steps 6 and 7 can be automated for more real-life scenarios using your, e.g. favourite CI/CD tooling.

6.8 Quick Restart Checklist

- From host operating system
 - Start dnsmasq Docker container
 - Start vagrant OpenShift box
- From Network Preferences
 - Note down the DNS servers supplied by your Network provider
 - Edit the DNS Server to be <DNS-IP> of your dnsmasq server
 - Verify Search domains contains cloudapps.example.com
- From host operating system
 - Edit ~/dnsmasq/dnsmasq.resolv.conf to use external DNS servers noted above
 - Verify with dig testdrive.cloudapps.example.com
- From guest operating system
 - vagrant ssh
 - su –
 - Verify with dig testdrive.cloudapps.example.com

7 Enhancements

7.1 To Do

- Cross-platform automation of configuration steps for IP addressing
- Offline/disconnected mode operation
 - For later Mac OS/X, virtual Ethernet mapping is a problem issues can be resolved by attaching a loopback Ethernet jack or equivalent (e.g. an ISP dongle)
- Use case for JBoss Developer Studio integration via oc port-forward
- Application of oc import-image to import images
- Demonstrate oc scale usage for weightwatcher2
- Add tags to images
- OpenShift image management tips and tricks
- Add EFK log aggregation and heapster for metrics capture
- Port to OpenShift Enterprise and JBoss BRMS as available
- Integrating external service endpoint with service object for FitBit or MySQL example
- m2 repository as common external localvol for workbench and weightwatcher pods
- Jenkins integration
- MySQL pod with localvol persistent storage
- Switch to rocker based R and RStudio containers

8 Work in Progress

8.1 Metrics Setup

```
// Create default config files
# openshift start --write-config=/openshift.local.config

// Edit settings
# vi /openshift.local.config/master/master-config.yaml
assetConfig:
  metricsPublicURL: https://hawkular-metrics.example.com/hawkular/metrics
  masterPublicURL: https://localhost:8443
  publicURL: https://localhost:8443/console/
corsAllowedOrigins:
- .*

// Launch from cmd line
# systemctl stop openshift
# openshift start --master-config=/openshift.local.config/master/master-
config.yaml --node-config=/openshift.local.config/node-
localhost.localdomain/node-config.yaml
```
